Name Period

1. Consider the following instance variable and method. Method wordsWithCommas is intended to return a string containing all the words in listOfWords separated by commas and enclosed in braces. For example, if listOfWords contains ["one", "two", "three"], the string returned by the call wordsWithCommas() should be "{one, two, three}".

(a) Identify the error in the code above with a circle. Write the corrected code below.

(b) Write one line of code that could replace /\* Modify the code \*/ to ensure the method works as intended.

/4

```
2. Consider the following code segment.
   /** @param wordList an ArrayList of String objects
    * @param word the word to be removed
    * Postcondition: All occurrences of word have been removed from
    * wordList.
    */
   public static ArrayList<String> removeWord(ArrayList<String> wordList,
   String word){
        for(int i = 0; i < wordList.size();i++){</pre>
              if(wordList.get(i).equals(word))
                   wordList.remove(i);
        }
   return wordList;
(a) Consider a wordList which contains the following values,
{bat
       dog cat sat
                         rat
                               rat rat}
What is returned when the following method is called?
removeWord(wordList, "rat")
                                                                                  /1
```

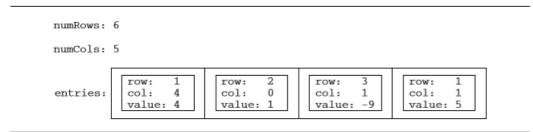

3. A two-dimensional array of integers in which most elements are zero is called a sparse array. Because most elements have a value of zero, memory can be saved by storing only the non-zero values along with their row and column indexes. The following complete SparseArrayEntry class is used to represent non-zero elements in a sparse array. A SparseArrayEntry object cannot be modified after it has been constructed. public class SparseArrayEntry { /\*\* The row index and column index for this entry in the sparse array \*/ private int row; private int col; /\*\* The value of this entry in the sparse array \*/ private int value; /\*\* Constructs a SparseArrayEntry object that represents a sparse array element with row index r and column index c, containing value v. \*/ public SparseArrayEntry(int r, int c, int v) { row = r;col = c;value = v;} /\*\* Returns the row index of this sparse array element. \*/ public int getRow() { return row; /\*\* Returns the column index of this sparse array element. \*/ public int getCol() return col; } /\*\* Returns the value of this sparse array element. \*/ public int getValue() return value; } }

```
The SparseArray class represents a sparse array. It contains a list of SparseArrayEntry objects, each of
which represents one of the non-zero elements in the array. The entries representing the non-zero elements
are stored in the list in no particular order. Each non-zero element is represented by exactly one entry in the
public class SparseArray {
/** The number of rows and columns in the sparse array. */
     private int numRows;
     private int numCols;
/** The list of entries representing the non-zero elements of the
 * sparse array. Entries are stored in the list in no particular order.
 * Each non-zero element is represented by exactly one entry in
 * the list.
     private ArrayList<SparseArrayEntry> entries;
/** Constructs an empty SparseArray. */
     public SparseArray()
          entries = new ArrayList<SparseArrayEntry>();
/** Returns the number of rows in the sparse array. */
     public int getNumRows()
          return numRows;
     }
/** Returns the number of columns in the sparse array. */
     public int getNumCols()
          return numCols;
     }
/** Returns the value of the element at row index row and column
  index col in the sparse array.
 * Precondition: 0 ≤ row < getNumRows()
   0 ≤ col < getNumCols()</pre>
*/
     public int getValueAt(int row, int col)
          /* implementation not shown */
     }
/** Returns the col in which the first instance of an element is found
 * Precondition: 0 ≤ col < getNumCols()
   0 ≤ col < getNumCols()
     public int findCol(int value)
          /* to be implemented in part (a) */
/** Removes the row from the sparse array.
 * Precondition: 0 ≤ row < getNumRows()
 */
     public void removeRow(int row)
          /* to be implemented in part (b) */
// There may be instance variables, constructors, and methods that are not
```

(a)	The following table shows an	example of a two-dimensional	sparse array. Empt	y cells in the table
	indicate zero values			

	0	1	2	3	4
0					
1		5			4
2	1				
3		-9			
4					
5					

The sample array can be represented by a SparseArray object, sparse, with the following instance variable values. The items in entries are in no particular order; one possible ordering is shown below.

Write the SparseArray method findCol. The method returns the col in which the first instance of the value is found. If there are no cols that contain the specified value, 0 is returned.

In the example above, the call sparse.findCol(-9) would return 1, and sparse.findCol(3) would return 0.

Complete method findCol below.

```
/** Returns the col in which the first instance of an element is found
    * Precondition: 0 ≤ col < getNumCols()
    * 0 ≤ row < getNumRows()
    */
public int findCol(int value)</pre>
```

- (b) Write the SparseArray method removeRow. After removing a specified row from a sparse array:
  - All entries in the list entries with row indexes matching row are removed from the list.
  - All entries in the list entries with row indexes greater than row are replaced by entries with row indexes that are decremented by one (moved one row to the up).
  - The number of rows in the sparse array is adjusted to reflect the row removed.

The sample object sparse from the beginning of the question is repeated for your convenience.

	0	1	2	3	4
0					
1			5		4
2	1				
3			-9		
4					
5					

The outlined entries below correspond to the shaded column above.

entries	row: 2	row: 1	row: 1	row: 3
	col: 0	col: 2	col: 4	col: 2
	value: 1	value 5	value: 4	value: -9

When sparse has the state shown above, the call <code>sparse.removeRow(1)</code> could result in sparse having the following values in its instance variables (since entries is in no particular order, it would be equally valid to reverse the order of its two items). The shaded areas below show the changes.

numRows: 5
numCols: 5

## entries:

row: 1 row: 2 col: 0 col: 2 value: 1 value: -9

numRows: 4
numCols: 5

Class information repeated from the beginning of the question

## public class SparseArrayEntry

```
public SparseArrayEntry(int r, int c, int v)
public int getRow()
public int getCol()
public int getValue()
```

```
public class SparseArray
private int numRows
private int numCols
private List<SparseArrayEntry> entries
public int getNumRows()
public int getNumCols()
public int getValueAt(int row, int col)
public void removeRow(int col)
public int findCol(int value)
Complete method removeRow below.
/** Removes the row from the sparse array.
* Precondition: 0 ≤ row < getNumRow()
*/
public void removeRow(int row)
                                                                             /5
```
